

Data Dictionary — Business Terms + Watch-Outs

Here's every table, explained like I'd walk a new analyst through our schema on day one.

district — Regional/branch demographics

Column	Business meaning
<code>district_id</code>	Region code — this is your join key between <code>account</code> and <code>client</code>
A2	District name
A3	Region name (broader area)
A4	Number of inhabitants
A5-A7	Municipality size breakdown (small/medium/large towns)
A8	Number of cities
A9	Ratio of urban inhabitants
A10	Average salary in the district
A11	Unemployment rate (1995)
A12	Unemployment rate (1996)
A13	Ratio of entrepreneurs
A14, A15	Crime counts (1995, 1996)
A16	Same, more recent

FLAG: Column names are just A2-A16, not descriptive — you'll want to rename them in SQL early on so your later queries are readable. Also check for ? as a value in a couple of these columns — that's how missing data was originally coded, not an actual `NULL`. You'll need to clean that before doing any math on these columns (a raw `AVG()` will error or misbehave if it's still a ? string).

account

Column	Business meaning
<code>account_id</code>	Primary key — your core join key everywhere
<code>district_id</code>	Where the account is based — joins to <code>district</code>
<code>frequency</code>	How often statements are issued; values are in Czech: <code>POPLATEK MESICNE</code> = monthly, <code>POPLATEK TYDNE</code> = weekly, <code>POPLATEK PO OBRATU</code> = after each transaction
<code>date</code>	Account opening date

FLAG: You already hit the Czech **frequency** issue — recode it early, it'll come up in every account-level query.

client

Column	Business meaning
client_id	Primary key
birth_number	Birth date of client
district_id	Client's home district

disp (disposition — who can operate an account)

Column	Business meaning
disp_id	Primary key
client_id	Which client
account_id	Which account
type	Relationship to the account — values: OWNER or DISPONENT (someone with access but not primary ownership)

FLAG: An account can have multiple **disp** rows (joint accounts). If you join **loan** → **account** → **disp** → **client** without care, you can accidentally **duplicate loan rows** when an account has 2 clients (owner + disponent). Decide upfront: are you analyzing at the *owner* level only, or all linked clients?

loan — your target table

Column	Business meaning
loan_id	Primary key
account_id	Which account took the loan
date	Loan issue date
amount	Total loan amount
duration	Loan term, in months
payments	Monthly installment amount
status	A = good, finished; B = defaulted, finished; C = good, still running; D = defaulted, still running

FLAG: Decide how you treat C (still running, currently fine). It's not a default *yet*, but it's also not a fully proven "good" loan the way A is. Most analyses either exclude C/D (only look at finished loans) or treat C as "good so far." State your choice explicitly in your notes — this is exactly the kind of assumption a real analyst has to document.

card

Column	Business meaning
card_id	Primary key
disp_id	Joins to disp (not directly to client or account — one more hop needed)
type	Card tier — junior , classic , gold
issued	Issue date

FLAG: Note the join path — **card** → **disp** → **account**. Easy to forget the extra hop.

order (standing/permanent payment orders)

Column	Business meaning
order_id	Primary key
account_id	Which account
bank_to	Recipient bank code
account_to	Recipient account
amount	Standing order amount
k_symbol	Purpose code — values like POJISTNE (insurance), SIPO (household payment), LEASING , UVER (loan payment) — also Czech, worth translating

trans — transaction history (your biggest table)

Column	Business meaning
trans_id	Primary key
account_id	Which account
date	Transaction date
type	PRIJEM = credit (money in), VYDAJ = withdrawal (money out)
operation	More detail: VYBER KARTOU (credit card withdrawal), VKLAD (cash deposit), PREVOD Z UCTU (transfer from another bank), VYBER (cash withdrawal), PREVOD NA UCET (transfer to another bank)
amount	Transaction amount
balance	Account balance <i>after</i> this transaction
k_symbol	Purpose code (similar to order)

Column	Business meaning
bank / account	Counterparty bank/account for transfers

FLAG: The `trans` table can be ~1 million rows. Every query touching it should filter by date range or a specific `account_id`.
